[1] This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

[1] Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

ABSTRACT

Nominal catches of cod from the 4RS 3Pn stock have increased in recent years from 74,000 t in 1977 to 105,000 in 1982 and to 103,000 t in 1983 (preliminary statistics). Catch rates were standardized to Canada-Maritime otter trawler TC4 using the multiplicative model combining catch rate data for country-gear, months, divisions and years. Standardized catch rate indices have increased in the same interval from 0.755 t/hour to 1.871 t/hour in 1982 and 1.668 t/hour in 1983. Exploitable biomass from cohort analysis (using a constant instantaneous rate of natural mortality of 0.2) provided the best relationship with catch rate series when a fully recruited fishing mortality of 0.275 was assumed for 1983. Projections for 1985 at $F_{0.1}$ indicated a catch of 90,000 t assuming that the TAC of 100,000 t will be taken in 1984.

RÉSUMÉ

Les captures nominales de morue provenant du stock de 4RS 3Pn ont augmenté au cours des dernières années de 74,000 t en 1977 à 105,000 t en 1982 et 103,000 t en 1983 (données préliminaires). Les taux de capture standardisés ont aussi augmenté au cours de la même période de 0.755 t/heure à 1.871 t/heure en 1982 et 1.688 t/heure en 1983. Les taux de captures ont été standardisé sur les chalutiers (TC4) canadiens des provinces maritimes en utilisant le modèle multiplicatif qui permet de combiner des données provenant de pays-engins, mois, divisions et années. La meilleure relation entre les taux de capture et les estimés de biomasse exploitable produit par des analyses de cohorte (avec un taux instantané constant de mortalité naturelle de 0.2) a été obtenue quand une mortalité par pêche $F_T = 0.275$ a été utilisée en 1983 sur les âges pleinement recrutés. Une prise de 90,000 t à $F_{0.1}$ a été prédite pour 1985 en supposant que le TPA de 100,000 t va être pris en 1984.

103-02554/

1. INTRODUCTION

The cod fishery in NAFO Divisions 3Pn, 4R and 4S has been prosecuted historically in two distinct components: a winter fishery on the southwest coast of Newfoundland (Divisions 3Pn and southern 4R) and a summer fishery in divisions 4R and 4S (Table 1). Landings from this cod stock have fluctuated between 58,200 and 105,000 t (Figure 1, Table 1). Between 1959 and 1976, Canadian catches have averaged 53% of the totals while French, Portuguese and other foreign fleets landed respectively 23%, 5% and 9% of the total catches (Table 2). Since 1977 the French component of the catch has been limited to 15% of the TAC while the remainder was caught in a 3 to 1 ratio by Newfoundland and Quebec based vessels. Catches by maritime based vessels have been relatively small (3-5%). A breakdown of the landings into main gear categories is given in Table 3.

2. NOMINAL CATCHES

The 1983 nominal catch statistics (Table 4) for Newfoundland and Maritime based vessels were obtained from the respective Statistics branches of the Department of Fisheries and Oceans. Catch statistics for the Quebec based vessel were obtained from Le Bureau de la Statistique du Québec and data for the French fleet operating in the Gulf were obtained through the FLASH system. Preliminary 1983 catch was estimated at 102,647 t, exceeding the TAC by 2,647 t. This represents a small decrease relative to the final 1982 catch of 104,939 t (Tables 2, 3). Allocations were reached or exceeded by all fleet components, with the exception of mobile gears operating in division 4S.

3. CATCH AND EFFORT DATA

Historical commercial catch and effort data, with the exception of Quebec based vessels, were obtained from the NAFO Statistical Bulletins. Historical catch and effort data for Quebec-based vessels (from 1975 onward) were obtained from the Direction de la recherche, ministère de l'Agriculture, des Pêcheries et de l'Alimentation du Québec (J.P. Lussia-Berdou, personnal communication). Data for 1983 were obtained with the nominal catch statistics.

The catch rate data were analysed using the multiplicative model (Gavaris, 1980). The series was analysed in a single unit as done in last year assessment (Gascon, 1983). Data entries with values of effort less than 10 hours, or catches of less than 10 tonnes were deleted from the data set because of possible large rounding off in the statistical tables. A weighting factor, estimated from the residuals of an unweighted regression (averaged on 5 levels of effort values) was applied to the CPUE data. Results of the analysis are presented in Tables 5 to 7 and in Figure 2.

Catch rate values have declined slightly in 1983 after having reached their highest levels in 1982.

4. RESEARCH SURVEY DATA

Biomass estimates of cod from the random stratified surveys conducted in Divisions 4R, 4S and 3Pn between 1978 and 1984 on the Gadus Atlantica are given in table 8. Biomass estimates were broken down into stratum surveyed on the particular trips. No survey was conducted in 1982. The surveys were all conducted in the January- February period. The coverage of Div. 4S is quite variable, owing to weather and ice conditions at that time of the year in the area. The results of the research surveys show high year to year variability; they indicate nonetheless a substantial increase in biomass between 1978 & 1984 (Fig. 3).

5. CATCH AT AGE

Biological sampling data of the catch were obtained from several sources: for Canadian landings from the Research branches of the Quebec and Gulf regions and "Corporation de développement des pêches" (CODEP) and the foreign Observer Program (Quebec region) for catches by the French Fleet (Table 9).

Quarterly catches at age were calculated for the main components of the fishery. Quarterly length frequencies for inshore gears and trawlers were obtained from a weighted (by nominal catch) average of monthly length frequencies for the different fleet components (Table 10). Quarterly catch at age for both inshore gears and trawlers were produced by applying the appropriate age-length keys to these lengths frequencies. These quarterly catch at ages were then combined to produce the catch at age vector for 1983 (Table 11). Average weights at age were obtained by applying the following length weight relationship to the length at age data (Hodder, 1964):

$$W_{kg} = 6.1575 \times 10^{-6} \times FL_{cm}^{3.087855}$$

The 1982 catch at age was updated using the final 1982 nominal catch statistics and the 1974-1981 catch at age was taken from Gascon (1983).

6. SEQUENTIAL POPULATION ANALYSIS

Virtual population analysis [VPA] (Gulland, in Pope, 1972) was performed using the catch at age matrix shown in Table 12a. By examination of the age specific mortality tables of preliminary runs of VPA, and from a

separable virtual population analysis (Pope and Shepherd, 1982), it appears that cod in NAFO Divisions 4RS 3Pn are fully recruited to the fishery at age 7 onward. The partial recruitments for ages 4, 5 and 6 were estimated as the average of partial recruitments for age 4 to 6 between 1974 and 1980 (Table 13). The partial recruitments in 1981 and 1982 were excluded as it appears that the fishery was aiming at the abundant 1977 and 1978 year classes (age 4 in 1981 and 1982 respectively). The historical partial recruitments were estimated as the ratio of the fishing mortality (Table 13) at age over the fully recruited fishing mortality from age 7 to 11. The fully recruited fishing mortality was estimated from the survival rate of fish aged 7 to 10 in one year and aged 8 to 11 in the next.

VPA were produced using values for F_T 0.15 to 0.45 (increments of 0.05) and .275, and the fully recruited fishing mortality as defined above for the oldest age group (15) in each year. The summary results of regression analysis between exploitable biomass calculated using average weights at age in Table 12b vs the standardized catch rates and fully recruited fishing mortality vs standardized effort are shown in table 14 and 15. Exploitable biomass was calculated by applying the partial recruitment vector (Table 13) to the total midyear biomass estimates derived from VPA (Table 16). Owing to the short time series, and the great variability in survey results, the research survey abundance indices could not be used for tuning the VPA. The relationships between exploitable biomass estimates from VPA at terminal $F_T = 0.275$ and standardized CPUE provided the regression line passing closest to the origin. Results of VPA at fully recruited $F = 0.275$ in the last year are shown in Table 16. The correlation coefficient had no discriminatory power for selecting F_T, because the distribution of observations (older year: low biomass, recent years high biomass levels) yielded essentially a 2-point regression.

The relationships between exploitable biomass and standardized catch rates, and fully recruited fishing mortality and standardized effort are shown in Figures 4 and 5.

7. CATCH PROJECTIONS

Catch projections were made using the populations numbers in 1983 from VPA at $F_T = 0.275$. Recruitment at age 4 in 1984 and 1985 was estimated as the geometric mean of recruitment from 1974 to 1980 (110×10^6 fish). The unusually large 1977 year class (age 4 in 1981) was excluded from the mean. The mean weights at age for 1984 and 1985 were estimated as the average of the mean weights between 1981 and 1983. Results of projections assuming $F_{0.1}$ (= 0.2) in 1984 and 1985 are shown in Table 17 while those assuming that the TAC for 1984 (100,000 t) will be taken and $F_{0.1}$ in 1985 are shown in Table 18. Under the latter set of assumptions, a catch of 90,000 t would result in 1985.

Table 11. Catch at age and average weights of cod in NAFO division 4R, 4S and 3Pn in 1983.

AGE	CATCH IN 1 000's	AVERAGE WEIGHT
2	11	0.10
3	199	0.41
4	1 701	0.88
5	9 061	1.26
6	21 130	1.58
7	11 362	1.91
8	7 561*	2.14
9	4 306	2.51
10	1 654	3.16
11	744	3.90
12	207	3.62
13	133	4.63
14	22	7.26
15	25	9.48
16	8	6.43
17	8	4.98
18	2	12.80

* An addition error was found in computing the total catch at age for age 11. 7180 x 10^3 fish were used in cohort analysis. VPA with this correct value at age 8 produces a 4+ total biomass of 641,000 t instead of 636 000 t.

Table 12a. Catch at age ($\times 10^{-3}$) matrix used in sequential population analysis.

b. Mean weights at age for cod in NAFO Divisions 4RS 3Pn.
